

- 27 Papain is an enzyme that tenderises meats by hydrolysing proteins in meat into smaller polypeptides and amino acids. It specifically hydrolyses the peptide bond on the carboxyl side of a residue that contains a nitrogen in the side chain. For example, the polypeptide R is hydrolysed into S, T and U.

Which of the four tetrapeptides on the page 17 will form two different **dipeptides** when hydrolysed by papain?

D
