

Its symbol is Ts and it is found in Group 17 of the Periodic Table below element 85, astatine, whose symbol is At.

Chemists are still uncertain about the properties of tennessine, but it is expected that one form of the element will exist as Ts_2 molecules, and that this form of tennessine will be a solid under room conditions.

Which statement about the volatility of Ts_2 can be predicted on the basis of the trends in Group 17?

- A** Ts_2 is less volatile than At_2 because of greater instantaneous dipole-induced dipole attractions in Ts_2 .
- B** Ts_2 is less volatile than At_2 because the Ts–Ts bond is longer than the At–At bond.
- C** Ts_2 is more volatile than At_2 because of greater instantaneous dipole-induced dipole
